Abstract

This paper considers in the high dimensional setting a canonical testing problem, namely testing the equality of multiple mean vectors of normal distribution. Motivated by Roy's union-intersection principal, we propose a generalized likelihood ratio test. The critical value is determined by permutation method. We introduce an algorithm for permuting procedure, whose complexity does not depend on data dimension. The limiting distribution of the test statistic is derived in two different setting: non-spiked covariance and spiked covariance. Theoretical results and simulation studies show that the test is particularly powerful under spiked covariance.

1. Introduction

Suppose we have independent observations $X_{ij} \in \mathbb{R}^p$ ($j = 1, \dots, n_k$; $i = 1, \dots, K$) with distribution $N_p(\mu_i, \Sigma)$, where μ_i , $i = 1, \dots, K$, and $\Sigma > 0$ are

unknown. We would like to test

$$H : \mu_1 = \mu_2 = \cdots = \mu_k \quad \text{v.s.} \quad K : \mu_i \neq \mu_j \text{ for some } i \neq j. \quad (1)$$

The problem is known as one-way multivariate analysis of variance (MANOVA). There are four classical tests for hypothesis (1): Wilks' Lambda (which is also the LRT), Hotelling-Lawley trace, Pillai Trace and Roy's maximum root.

In some modern scientific applications, people would like to test hypothesis (1) in high dimensional setting, i.e., p is greater than $n = \sum_{i=1}^K n_i$. See, for example, [1]. However, when $p > n - K$, the LRT for hypothesis (1) is not well defined. Researchers have done extensive work to study the testing problem (1) in high dimensional setting. So far, most tests in the literature are designed for two sample case, i.e. $K = 2$. See, for example, [2], [3], [4], [5] and [6]. For the multiple sample case, [7] modified the Dempster's trace test and proposed a test statistic

$$T_{SC} = \frac{1}{\sqrt{n-1}} \left(\frac{1}{K-1} \text{tr} \left(\sum_{i=1}^K n_i \bar{X}_i \bar{X}_i^T - n \bar{X} \bar{X}^T \right) - \frac{1}{n-K} \text{tr} \left(\sum_{i=1}^K \sum_{j=1}^{n_i} X_{ij} X_{ij}^T - \sum_{i=1}^K n_i \bar{X}_i \bar{X}_i^T \right) \right),$$

where $\bar{X}_i = n_i^{-1} \sum_{j=1}^{n_i} X_{ij}$ and $\bar{X} = n^{-1} \sum_{i=1}^K \sum_{j=1}^{n_i} X_{ij}$. In another work, [8] proposed a test statistic

$$T_{CX} = \max_{1 \leq i \leq p} \sum_{1 \leq j < l \leq K} \frac{n_j n_l}{n_j + n_l} \frac{(\Omega(\bar{X}_j - \bar{X}_l))_i^2}{\omega_{ii}},$$

5 Where $\Omega = (\omega)_{ij} = \Sigma^{-1}$ is the precision matrix. When Ω is unknown, they substitute it by an estimator $\hat{\Omega}$. Statistics T_{SC} and T_{CX} are the representatives of two popular methodologies for high dimensional tests. T_{SC} is a so-called sum-of-squares type statistic as it is based on an estimation of squared Euclidean norm $\sum_{i=1}^K n_i \|\mu_i - \bar{\mu}\|^2$, where $\bar{\mu} = n^{-1} \sum_{i=1}^K n_i \mu_i$. T_{CX} is an extreme value
10 type statistic.

Note that both sum-of-squares type statistic and extreme value type statistic are not based on likelihood function. It remains a problem how to construct likelihood-based tests in high dimensional setting. In a recent work, [9] proposed a generalized likelihood ratio test in the context of one-sample mean vector test.

15 Inspired by Roy's union-intersection tests ([10]), they write the null hypothesis
as the intersection of a class of component hypotheses. For each component
hypotheses, the likelihood ratio test is constructed. Using a least favorable
argument, they construct a test statistics based on these tests. Their simulation
results showed that their test has particular good power performance when the
20 variables are dependent.

Following [9]'s methodology, we proposed a generalized likelihood ratio test
for hypothesis (1). Most existing tests for hypothesis (1) imposed conditions
which prevent from large leading eigenvalues of Σ . However, when the corre-
lations between variables are determined by a small number of factors, Σ is
25 spiked in the sense that a few leading eigenvalues are much larger than the
others. See, for example [11] and [12]. We derive the asymptotic distribution of
the test statistic under both spiked and non-spiked covariance. Our theoretical
results imply that the new test is particularly powerful under spiked covariance.
We conduct a simulation study to examine the numerical performance of the
30 test.

The rest of the paper is organized as follows.

Higher criticism CX are special case of UIT.

2. Methodology

2.1. Roy's maximum root

Roy's maximum root test statistic is derived in [10] as an example of Roy's
union intersection principle. The idea of Roy's union intersection principle is
to reduce testing problem to a class of pseudo-univariate problems. For $a \in \mathbb{R}^p$
and $a^T a = 1$, define the hypothesis H_a and K_a as

$$H_a : a^T \mu_1 = a^T \mu_2 = \cdots = a^T \mu_k \quad \text{v.s.} \quad K : a^T \mu_i \neq a^T \mu_j \text{ for some } i \neq j.$$

Then the hypothesis (1) $H = \cap_a H_a$. The union-intersection principle tells that
 H is rejected if and only if any one of H_a is rejected. Let $\mathbf{X}_i = (X_{i1}, \dots, X_{in_i})$

be the i th sample, $i = 1, \dots, K$. Let $\mathbf{Z} = (\mathbf{X}_1, \dots, \mathbf{X}_K)$ be the pool sample.

Note that the likelihood function based on $a^T \mathbf{Z}$ is

$$f_a(a^T \mathbf{Z}; \mu_1, \dots, \mu_k, \Sigma) = (2\pi)^{-n/2} |a^T \Sigma a|^{-n/2} \exp \left(-\frac{1}{2a^T \Sigma a} \sum_{i=1}^K \sum_{j=1}^{n_i} (a^T X_{ij} - a^T \mu_i)^2 \right).$$

The likelihood ratio test statistic for H_a v.s. K_a (which is also uniformly most powerful unbiased test) is

$$\text{LRT}_a = \frac{\max_{\mu_1, \dots, \mu_k, \Sigma} f_a(a^T \mathbf{Z}, \mu_1, \dots, \mu_k, \Sigma)}{\max_{\mu, \Sigma} f_a(a^T \mathbf{Z}, \mu, \dots, \mu, \Sigma)} = \left(1 + \frac{a^T F a}{a^T G a} \right)^{n/2},$$

where $G = \sum_{i=1}^K \sum_{j=1}^{n_i} (X_{ij} - \bar{\mathbf{X}}_i)(X_{ij} - \bar{\mathbf{X}}_i)^T$ and $F = \sum_{i=1}^K n_i (\bar{\mathbf{X}}_i - \bar{\mathbf{X}})(\bar{\mathbf{X}}_i - \bar{\mathbf{X}})^T$. Follow the type II method of [10], the union intersection test statistic is $\max_{a^T a=1} \text{LRT}_a = (1 + \lambda_{\max}(FG^{-1}))^{n/2}$ which is an increase function of $\lambda_{\max}(FG^{-1})$, Roy's maximum root test statistic. Note that here we need the assumption $p \leq n - K$, or else G is not invertible.

2.2. The new test statistic

We are interested in the case when $p > n - K$. In this setting, $\max_{a^T a=1} \text{LRT}_a = +\infty$ and Roy's maximum root test is not defined. In another viewpoint, union intersection principal finds an direction a along which the evidence against null hypothesis is maximized. Such an a is data dependent. In the classical setting, the evidence of direction a is LRT_a . In the current context, there are a class of a such that LRT_a achieve the infinity, the largest evidence in classical sense. We need to further choose a single a from $\{a \mid \text{LRT}_a = +\infty \text{ and } a^T a = 1\}$. From the expression of LRT_a , we would like to make the largest discrepancy between $a^T F a$ and $a^T G a$. Note that if $\text{LRT}_a = +\infty$, then $a^T G a = 0$. Hence it's natural to choose a as

$$a^* = \arg \max_{a^T a=1, a^T G a=0} a^T F a.$$

Since $a^{*T} G a^* = 0$, we propose the following test statistic for H :

$$T = a^{*T} F a^* = \max_{a^T a=1, a^T G a=0} a^T F a.$$

When T is large enough, we reject H . The above strategy is first proposed by [9] in the context of testing one sample mean vector.

Next we derive the explicit forms of the test statistic. Let $J = \text{diag}(n_1^{-1/2}\mathbf{1}_{n_1}, \dots, n_k^{-1/2}\mathbf{1}_{n_k})$. Then the matrices $I_n - JJ^T$, $JJ^T - \frac{1}{n}\mathbf{1}_n\mathbf{1}_n^T$ and $\frac{1}{n}\mathbf{1}_n\mathbf{1}_n^T$ are three $n \times n$ projection matrices which are pairwise orthogonal with rank $n - k$, $k - 1$ and 1. Let \tilde{J} be a $n \times (n - k)$ matrix satisfying $\tilde{J}\tilde{J}^T = I - JJ^T$. Note that $I_k - \frac{1}{n}J^T\mathbf{1}_n\mathbf{1}_n^T J$ is a $k \times k$ projection matrix with rank $k - 1$. Let C be a $k \times (k - 1)$ matrix satisfying $CC^T = I_k - \frac{1}{n}J^T\mathbf{1}_n\mathbf{1}_n^T J$. Then

$$G = Z(I_n - JJ^T)Z^T = Z\tilde{J}\tilde{J}^T Z^T.$$

and

$$F = \sum_{i=1}^k n_i(\bar{\mathbf{X}}_i - \bar{\mathbf{X}})(\bar{\mathbf{X}}_i - \bar{\mathbf{X}})^T = Z(JJ^T - \frac{1}{n}\mathbf{1}_n\mathbf{1}_n^T)Z^T = ZJ(I_k - \frac{1}{n}J^T\mathbf{1}_n\mathbf{1}_n^T J)J^T Z^T = ZJCC^T J^T Z^T.$$

Let $Z\tilde{J} = U_{Z\tilde{J}}D_{Z\tilde{J}}V_{Z\tilde{J}}^T$ be the singular value decomposition of $Z\tilde{J}$, where $U_{Z\tilde{J}}$ and $V_{Z\tilde{J}}$ are $p \times (n - K)$ and $(n - K) \times (n - K)$ column orthogonal matrices respectively, $D_{Z\tilde{J}}$ is $(n - K) \times (n - K)$ diagonal matrix. Let $H_{Z\tilde{J}} = U_{Z\tilde{J}}U_{Z\tilde{J}}^T$ be the projection on the column space of A . Then by Proposition 1,

$$T = \lambda_{\max}(ZJCC^T J^T Z^T(I_p - H_{Z\tilde{J}})) = \lambda_{\max}(C^T J^T Z^T(I_p - H_{Z\tilde{J}})ZJC). \quad (2)$$

Next we introduce another form of T . By the relationship

$$\begin{pmatrix} J^T Z^T ZJ & J^T Z^T Z\tilde{J} \\ \tilde{J}^T Z^T ZJ & \tilde{J}^T Z^T Z\tilde{J} \end{pmatrix}^{-1} = \left(\begin{pmatrix} J^T \\ \tilde{J}^T \end{pmatrix} Z^T Z \begin{pmatrix} J & \tilde{J} \end{pmatrix} \right)^{-1} = \begin{pmatrix} J^T(Z^T Z)^{-1}J & J^T(Z^T Z)^{-1}\tilde{J} \\ \tilde{J}^T(Z^T Z)^{-1}J & \tilde{J}^T(Z^T Z)^{-1}\tilde{J} \end{pmatrix}$$

and matrix inverse formula, we have that

$$(J^T(Z^T Z)^{-1}J)^{-1} = J^T Z^T ZJ - J^T Z^T Z\tilde{J}(\tilde{J}^T Z^T Z\tilde{J})^{-1}\tilde{J}^T Z^T ZJ = J^T Z^T(I_p - H_{Z\tilde{J}})ZJ.$$

Thus,

$$T(Z) = \lambda_{\max}(C^T(J^T(Z^T Z)^{-1}J)^{-1}C). \quad (3)$$

While the form (2) is used for theoretical analysis, the form (3) is well suited for computation, as we shall see.

Permutation method is a powerful tool to determine the critical value of a test statistic. The test procedure resulting from permutation method is exact as long as the null distribution of observations are exchangeable. See, for example, [13]. The major down-side to permutation method is that it can be computationally intensive. Fortunately, for our statistic, there is a fast implementation of the permutation method. Infact, using expression (3), a permutation for our statistic can be written by

$$T^* = \lambda_{\max} \left(C^T (J^T K^T (Z^T Z)^{-1} K J)^{-1} C \right). \quad (4)$$

for a random $n \times n$ permutation matrix K . Note that $(Z^T Z)^{-1}$, the most time-consuming component, can be calculated beforehand. The permutation procedure for our statistic can be summarized as:

- (I) Calculate $T(Z)$ according to (3), hold intermediate result $(Z^T Z)^{-1}$.
- 50 (II) Generate a random $n \times n$ permutation matrix K and calculate $T^*(Z)$ according to (4). Repeat M times to obtain $T_1^*(Z), \dots, T_M^*(Z)$.
- (III) Calculate the p -value by $\tilde{p} = (M + 1)^{-1} [1 + \sum_{i=1}^M I\{T_i^*(Z) \geq T(Z)\}]$.

Here M is the permutation times. It can be shown that for any integer $M > 0$, the resulting test controls the Type I error, more precisely, $\Pr(\tilde{p} \leq u) \leq u$ for all $0 \leq u \leq 1$. Moreover, as M tends to ∞ , $\lim_{M \rightarrow \infty} \Pr(\tilde{p} \leq u) = u$. See, for example, [14], Chapter 15.

It can be seen that the time complexities of step (I) and step (II) are $O(n^2 p + n^3)$ and $O(n^2 M)$, respectively. In large sample or high dimensional setting, $M/(p + n)$ is small. In this case, the permutation procedure has negligible effect on total time complexity.

3. Theory

In this section, we investigate the asymptotic behavior of our test statistic when p is much larger than n . More precisely, we shall assume $p/n \rightarrow \infty$.

In high dimensional setting, it is a common phenomenon that the asymptotic
65 distribution of statistic relies on the covariance structure. See, for example, [15]
and Rui Wang's paper. We shall investigate the asymptotics of our statistic
under two different covariance structures: non-spiked covariance and spiked
covariance.

Let $\Sigma = U\Lambda U^T$ be the eigenvalue decomposition of Σ , where $\Lambda = \text{diag}(\lambda_1, \dots, \lambda_p)$.

Theorem 1. Assume $p/n \rightarrow \infty$, $c \leq \lambda_p(\Lambda) \leq \dots \leq \lambda_1(\Lambda) \leq C$ and

$$\frac{p}{n^2} \rightarrow \infty.$$

Under local alternative

$$\frac{1}{p} \|\mu_f\|_F^2 \rightarrow 0,$$

we have

$$\left(2 \text{tr}(\Lambda^2)\right)^{-1/2} \left(C^T J^T Z^T (I_p - H_{Z\bar{J}}) Z J C - \text{tr}(\Lambda) I_{k-1} - \mu_f^T (I_p - H_{Z\bar{J}}) \mu_f\right) \xrightarrow{L} W_{k-1}.$$

70 The spiked covariance model assumes that a few eigenvalues of Σ are signifi-
cantly larger than the others. This model is a standard model in many problems
and takes factor model as a special case. See, for example,.

Assumption 1. Let r be a fixed integer. Assume $\lambda_r n/p \rightarrow \infty$ and $C \geq$
 $\lambda_{r+1} \geq \dots \geq \lambda_p \geq c$, where c and C are absolute constant.

Let $U = (U_1, U_2)$ where U_1 is $p \times r$ and U_2 is $p \times (p - r)$. Let $\Lambda_1 =$
 $\text{diag}(\lambda_1, \dots, \lambda_r)$ and $\Lambda_2 = \text{diag}(\lambda_{r+1}, \dots, \lambda_p)$. Then $\Sigma = U_1 \Lambda_1 U_1^T + U_2 \Lambda_2 U_2^T$.
Let

$$\mu_f \stackrel{\text{def}}{=} E(ZJC) = (\sqrt{n_1} \mu_1, \dots, \sqrt{n_k} \mu_k) C.$$

Theorem 2. Suppose $p/n \rightarrow \infty$. Assume Assumption (1) holds. Further
more, assume

$$\frac{\lambda_1^2 p}{\lambda_r^2 n^2} \rightarrow 0. \tag{5}$$

Then under local alternative

$$\frac{1}{\sqrt{p}} \|\mu_f\|_F^2 = O(1), \tag{6}$$

we have

$$(2c^2(p-r-n+k))^{-1/2} (C^T J^T Z^T (I_p - H_{Z\bar{J}}) Z J C - c(p-r-n+k) I_{k-1} - \mu_f^T (I_p - H_{Z\bar{J}}) \mu_f) \xrightarrow{\mathcal{L}} W_{k-1}, \quad (7)$$

75 where W_{k-1} is a $(k-1) \times (k-1)$ symmetric random matrix whose entries above the main diagonal are i.i.d. $N(0, 1)$ and the entries on the diagonal are i.i.d. $N(0, 2)$.

4. Simulation Results

In this section, we evaluate the numerical performance of the new test. For
80 comparison, we also carried out simulation for the test of Tony Cai and Yin Xia and the test of Schott. These tests are denoted respectively by NEW, CX and SC.

In the simulations, we set $k = 3$. Note that the new test is invariant under orthogonal transformation. Without loss of generality, we only consider diagonal Σ . We set $\Sigma = \text{diag}(p, 1, \dots, 1)$. Define signal-to-noise ratio (SNR) as

$$\text{SNR} = \frac{\|\mu_f\|_F^2}{\sqrt{\sum_{i=2}^p \lambda_i(\Sigma)^2}}.$$

We use SNR to characterize the signal strength. We consider two alternative hypotheses: the non-sparse alternative and the sparse alternative. In the non-
85 sparse case, we set $\mu_1 = \kappa 1_p$, $\mu_2 = -\kappa 1_p$ and $\mu_3 = 0_p$, where κ is selected to make the SNR equal to the given value. In the sparse case, we set $\mu_1 = \kappa(1_{p/5}^T, 0_{4p/5}^T)^T$, $\mu_2 = \kappa(0_{p/5}^T, 1_{p/5}^T, 0_{3p/5}^T)^T$ and $\mu_3 = 0_p$. Again, κ is selected to make the SNR equal to the given value.

5. Appendix

Proposition 1. Suppose A is a $p \times r$ matrix with rank r and B is a $p \times p$ non-zero semi-definite matrix. Denote by $A = U_A D_A V_A^T$ the singular value decomposition of A , where U_A and V_A are $p \times r$ and $r \times r$ column orthogonal

Table 1: Empirical powers of tests under non-sparse alternative with $\alpha = 0.05$, $k = 3$, $n_1 = n_2 = n_3 = 10$. Based on 1000 replications.

matrix, D_A is a $r \times r$ diagonal matrix. Let $H_A = U_A U_A^T$ be the projection on the column space of A . Then

$$\max_{a^T a=1, a^T A A^T a=0} a^T B a = \lambda_{\max}(B(I_p - H_A)). \quad (8)$$

Proof. Note that $a^T A A^T a = 0$ is equivalent to $H_A a = 0$ which in turn is equivalent to $a = (I_p - H_A)a$. Then

$$\max_{a^T a=1, a^T A A^T a=0} a^T B a = \max_{a^T a=1, H_A a=0} a^T (I_p - H_A) B (I_p - H_A) a, \quad (9)$$

90 which is obviously no greater than $\lambda_{\max}((I - H_A)B(I - H_A))$. To prove that they are equal, without loss of generality, we can assume $\lambda_{\max}((I - H_A)B(I - H_A)) > 0$. Let α_1 be one eigenvector corresponding to the largest eigenvalue of $(I - H_A)B(I - H_A)$. Since $(I - H_A)B(I - H_A)H_A = (I - H_A)B(H_A - H_A) = O_{p \times p}$ and H_A is symmetric, the rows of H_A are eigenvectors of $(I - H_A)B(I - H_A)$
95 corresponding to eigenvalue 0. It follows that $H_A \alpha_1 = 0$. Therefore, α_1 satisfies the constraint of (9) and (9) is no less than $\lambda_{\max}((I - H_A)B(I - H_A))$. The conclusion now follows by noting that $\lambda_{\max}((I - H_A)B(I - H_A)) = \lambda_{\max}(B(I - H_A))$. □

100 *Proof of the main results.* It can be seen that ZJC is independent of $Z\tilde{J}$. Since $E(Z\tilde{J}) = O_{p \times (n-k)}$, we can write $Z\tilde{J} = U\Lambda^{1/2}G_1$, where G_1 is a $p \times (n - k)$ matrix with i.i.d. $N(0, 1)$ entries. We write $ZJC = \mu_f + U\Lambda^{1/2}G_2$, where G_2 is a $p \times (k - 1)$ matrix with i.i.d. $N(0, 1)$ entries.

Then

$$\begin{aligned} C^T J^T Z^T (I_p - H_{Z\tilde{J}}) ZJC &= G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) U \Lambda_{1/2} G_2 + \mu_f^T (I_p - H_{Z\tilde{J}}) \mu_f + \\ &\quad \mu_f^T (I_p - H_{Z\tilde{J}}) U \Lambda^{1/2} G_2 + G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) \mu_f. \end{aligned} \quad (10)$$

The first term of (10) can be represented as

$$G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) U \Lambda_{1/2} G_2 = \sum_{i=1}^p \lambda_i (\Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) U \Lambda^{1/2}) \xi_i \xi_i^T, \quad (11)$$

where $\xi_i \stackrel{i.i.d.}{\sim} N(0, I_{k-1})$.

Proof of Theorem 1. First we deal with the first term of (10). Note that for $i = 1, \dots, p$, we have

$$\lambda_i(\Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda^{1/2}) \leq \lambda_i(\Lambda) \leq C. \quad (12)$$

For $i = 1, \dots, p - n$, by Weyl's inequality, we have

$$\lambda_i(\Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda^{1/2}) \geq \lambda_{i+n}(\Lambda) \geq c. \quad (13)$$

Then we have

$$\frac{\lambda_1^2(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})}{\sum_{i=1}^p \lambda_i^2(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})} \leq \frac{C}{c(p-n)} \rightarrow 0.$$

Apply Lyapunov central limit theorem conditioning on $Z\tilde{J}$, we have

$$\begin{aligned} & \left(2 \sum_{i=1}^p \lambda_i^2(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})\right)^{-1/2} \\ & \left(G_2^T \Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda_{1/2}G_2 - \sum_{i=1}^p \lambda_i(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})I_{k-1}\right) \xrightarrow{\mathcal{L}} W_{k-1}. \end{aligned}$$

Also by (12) and (13), we have

$$\sum_{i=n+1}^p \lambda_i^2 \leq \text{tr}[(\Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda^{1/2})^2] \leq \text{tr}(\Lambda^2).$$

Hence we have

$$\text{tr}[(\Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda^{1/2})^2] = \text{tr}(\Lambda^2) + O_P(n).$$

Similarly, we have

$$\text{tr}(\Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda^{1/2}) = \text{tr}(\Lambda) + O_P(n).$$

It follows that

$$\begin{aligned} & \left(2 \sum_{i=1}^p \lambda_i^2(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})\right)^{-1/2} \\ & \left(G_2^T \Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda_{1/2}G_2 - \sum_{i=1}^p \lambda_i(\Lambda^{1/2}U^T(I_p - H_{Z\bar{Z}})U\Lambda^{1/2})I_{k-1}\right) \\ & = \left(2(1 + O_P\left(\frac{n}{p}\right)) \text{tr}(\Lambda^2)\right)^{-1/2} \left(G_2^T \Lambda^{1/2}U^T(I_p - H_{Z\bar{J}})U\Lambda_{1/2}G_2 - (\text{tr}(\Lambda) + O_P(n))I_{k-1}\right) \end{aligned}$$

By Slutsky's theorem and the assumption $p/n^2 \rightarrow \infty$, we have that

$$\left(2 \operatorname{tr}(\Lambda^2)\right)^{-1/2} \left(G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\bar{J}}) U \Lambda_{1/2} G_2 - \operatorname{tr}(\Lambda) I_{k-1}\right) \xrightarrow{\mathcal{L}} W_{k-1}$$

Note that

$$\begin{aligned} & \mathbb{E} [\|\mu_f^T (I_p - H_{Z\bar{J}}) U \Lambda^{1/2} G_2\|_F^2] \\ &= (k-1) \mathbb{E} [\operatorname{tr} (\mu_f^T (I_p - H_{Z\bar{J}}) U \Lambda U^T (I_p - H_{Z\bar{J}}) \mu_f)] \\ &\leq (k-1) \mathbb{E} [\lambda_1 ((I_p - H_{Z\bar{J}}) U \Lambda U^T (I_p - H_{Z\bar{J}}))] \|\mu_f\|_F^2 \\ &\leq (k-1) \lambda_1(\Lambda) \|\mu_f\|_F^2 \leq (k-1) C \|\mu_f\|_F^2 = o(p). \end{aligned}$$

105 The conclusion follows. \square

Proof of Theorem 2. The asymptotic behavior of the first term of (10) relies on the positive eigenvalues of $\Lambda^{1/2} U^T (I_p - H_{Z\bar{J}}) U \Lambda^{1/2}$, which are equal to the eigenvalues of $(I_p - H_{Z\bar{J}}) U \Lambda U^T (I_p - H_{Z\bar{J}})$. Write $(I_p - H_{Z\bar{J}}) U \Lambda U^T (I_p - H_{Z\bar{J}})$ as the sum of two terms

$$\begin{aligned} & (I_p - H_{Z\bar{J}}) U \Lambda U^T (I_p - H_{Z\bar{J}}) \\ &= (I_p - H_{Z\bar{J}}) U_1 \Lambda_1 U_1^T (I_p - H_{Z\bar{J}}) + (I_p - H_{Z\bar{J}}) U_2 \Lambda_2 U_2^T (I_p - H_{Z\bar{J}}) \stackrel{def}{=} R_1 + R_2. \end{aligned}$$

Note that

$$\begin{aligned} \lambda_{\max}(R_1) &= \lambda_{\max}(\Lambda_1^{1/2} U_1^T (I_p - H_{Z\bar{J}}) U_1 \Lambda_1^{1/2}) \leq \lambda_{\max}(\Lambda_1^{1/2} U_1^T (I_p - U_{Z\bar{J}[1:r]}) U_{Z\bar{J}[1:r]}^T) U_1 \Lambda_1^{1/2}) \\ &\leq \lambda_1 \lambda_{\max}(U_1^T (I_p - U_{Z\bar{J}[1:r]}) U_{Z\bar{J}[1:r]}^T U_1) = \lambda_1 \lambda_{\max}(I_r - U_1^T U_{Z\bar{J}[1:r]} U_{Z\bar{J}[1:r]}^T U_1). \end{aligned}$$

To investigate the behavior of $U_{Z\bar{J}}$, we need to investigate the behavior of $D_{Z\bar{J}}$ first. Note that $G_1^T \Lambda G_1 = \tilde{J}^T Z^T Z \tilde{J} = V_{Z\bar{J}} D_{Z\bar{J}}^2 V_{Z\bar{J}}^T$, and $G_1^T \Lambda G_1 = G_{1[1:r]}^T \Lambda_1 G_{1[1:r]} + G_{1[(r+1):p]}^T \Lambda_2 G_{1[(r+1):p]}$. We have

$$V_{Z\bar{J}} D_{Z\bar{J}}^2 V_{Z\bar{J}}^T = G_{1[1:r]}^T \Lambda_1 G_{1[1:r]} + G_{1[(r+1):p]}^T \Lambda_2 G_{1[(r+1):p]}.$$

For $i = 1, \dots, r$,

$$\begin{aligned} \lambda_i(G_{1[1:r]}^T \Lambda_1 G_{1[1:r]}) &\geq \lambda_i(G_{1[1:r]}^T \operatorname{diag}(\lambda_i I_i, O_{(r-i) \times (r-i)}) G_{1[1:r]}) \\ &= \lambda_i \lambda_i(G_{1[1:i]} G_{1[1:i]}^T) = \lambda_i n(1 + o_P(1)), \end{aligned} \tag{14}$$

where the last equality holds since $n^{-1}G_{1[1:i,]}G_{1[1:i,]}^T \xrightarrow{P} I_i$ by law of large numbers. On the other hand, for $i = 1, \dots, r$,

$$\begin{aligned}
& \lambda_i(G_{1[1:r,]}^T \Lambda_1 G_{1[1:r,]}) \\
&= \lambda_i \left(G_{1[1:r,]}^T \left(\text{diag}(\lambda_1, \dots, \lambda_{i-1}, O_{(r-i+1) \times (r-i+1)}) + \text{diag}(O_{(i-1) \times (i-1)}, \lambda_i, \dots, \lambda_r) \right) G_{1[1:r,]} \right) \\
&\leq \lambda_1(G_{1[1:r,]}^T \text{diag}(O_{(i-1) \times (i-1)}, \lambda_i, \dots, \lambda_r) G_{1[1:r,]}) \leq \lambda_1(G_{1[1:r,]}^T \text{diag}(O_{(i-1) \times (i-1)}, \lambda_i I_{r-i+1}) G_{1[1:r,]}) \\
&= \lambda_i \lambda_1 (G_{1[i:r,]} G_{1[i:r,]}^T) = \lambda_i n(1 + o_P(1))
\end{aligned} \tag{15}$$

where the first inequality holds by Weyl's inequality. It follows from (14)

and (15) that $\lambda_i(G_{1[1:r,]}^T \Lambda_1 G_{1[1:r,]}) = \lambda_i n(1 + o_P(1))$ for $i = 1, \dots, r$.

Note that $\lambda_{\max}(G_{1[(r+1):p,]}^T \Lambda_2 G_{1[(r+1):p,]}) = c \lambda_{\max}(G_{1[(r+1):p,]}^T G_{1[(r+1):p,]}) = O_P(p)$ by Bai-Yin's law. By assumption $\lambda_r n/p \rightarrow \infty$, we can deduce that

$$D_{Z\tilde{J}[i,i]}^2 = \lambda_i(G_1^T \Lambda G_1) = \lambda_i n(1 + o_P(1)), \quad i = 1, \dots, r.$$

Now we are ready to investigate the behavior of $U_{Z\tilde{J}}$. Since $U \Lambda^{1/2} G_1 G_1^T \Lambda^{1/2} U^T = U_{Z\tilde{J}} D_{Z\tilde{J}}^2 U_{Z\tilde{J}}^T$, we have $G_1 G_1^T = \Lambda^{-1/2} U^T U_{Z\tilde{J}} D_{Z\tilde{J}}^2 U_{Z\tilde{J}}^T U \Lambda^{-1/2}$, which further indicates

$$\begin{aligned}
& G_{1[(r+1):p,]} G_{1[(r+1):p,]}^T = \Lambda_2^{-1/2} U_{[(r+1):p,]}^T U_{Z\tilde{J}} D_{Z\tilde{J}}^2 U_{Z\tilde{J}}^T U_{[(r+1):p,]} \Lambda_2^{-1/2} \\
&\geq \Lambda_2^{-1/2} U_{[(r+1):p,]}^T U_{Z\tilde{J}[1:r,]} D_{Z\tilde{J}[1:r,]}^2 U_{Z\tilde{J}[1:r,]}^T U_{[(r+1):p,]} \Lambda_2^{-1/2} \\
&\geq D_{Z\tilde{J}[r,r]}^2 \Lambda_2^{-1/2} U_{[(r+1):p,]}^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_{[(r+1):p,]} \Lambda_2^{-1/2}.
\end{aligned}$$

Thus,

$$\lambda_{\max}(U_{[(r+1):p,]}^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_{[(r+1):p,]}) \leq \frac{c}{D_{Z\tilde{J}[r,r]}^2} \lambda_1(G_{1[(r+1):p,]} G_{1[(r+1):p,]}^T) = O_P\left(\frac{p}{\lambda_r n}\right).$$

Note that we have the simple relationship

$$\begin{aligned}
& \lambda_{\max}(U_{[(r+1):p,]}^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_{[(r+1):p,]}) = \lambda_{\max}(U_{Z\tilde{J}[1:r,]}^T U_{[(r+1):p,]} U_{[(r+1):p,]}^T U_{Z\tilde{J}[1:r,]}) \\
&= \lambda_{\max}(U_{Z\tilde{J}[1:r,]}^T (I_p - U_1 U_1^T) U_{Z\tilde{J}[1:r,]}) = \lambda_{\max}(I_r - U_{Z\tilde{J}[1:r,]}^T U_1 U_1^T U_{Z\tilde{J}[1:r,]}) \\
&= 1 - \lambda_{\min}(U_{Z\tilde{J}[1:r,]}^T U_1 U_1^T U_{Z\tilde{J}[1:r,]}) = 1 - \lambda_{\min}(U_1^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_1) \\
&= \lambda_{\max}(I_r - U_1^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_1).
\end{aligned}$$

Therefore $\lambda_{\max}(I_r - U_1^T U_{Z\tilde{J}[1:r,]} U_{Z\tilde{J}[1:r,]}^T U_1) = O_P(\frac{p}{\lambda_r n})$, and we can conclude

$$\lambda_{\max}(R_1) = O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right).$$

We now deal with $R_1 + R_2$. For $i = 1, \dots, r$,

$$\lambda_i(R_1 + R_2) \leq \lambda_1(R_1 + R_2) \leq \lambda_1(R_1) + \lambda_1(R_2) = O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right) + c.$$

For $i = r + 1, \dots, p - r$,

$$\lambda_i(R_1 + R_2) \leq \lambda_{i-r}(R_2) = \lambda_{i-r}(\Lambda_2^{1/2} U_2^T (I_p - H_{Z\bar{J}}) U_2 \Lambda_2^{1/2}) = c \lambda_{i-r}(I_{p-r} - U_2^T H_{Z\bar{J}} U_2).$$

Since $U_2^T H_{Z\bar{J}} U_2$ has rank $n - k$, we have $\lambda_i(R_1 + R_2) \leq c$ for $r + 1 \leq i \leq p - n + k$ and $\lambda_i(R_1 + R_2) = 0$ for $p - n + k + 1 \leq i \leq p - r$. On the other hand, for $i = 1, \dots, p - r - n + k$,

$$\begin{aligned} \lambda_i(R_1 + R_2) &\geq \lambda_i(R_2) = \lambda_i(\Lambda_2^{1/2} U_2^T (I_p - H_{Z\bar{J}}) U_2 \Lambda_2^{1/2}) \\ &= c \lambda_i(I_{p-r} - U_2^T H_{Z\bar{J}} U_2) = c. \end{aligned}$$

The last equality holds since $U_2^T H_{Z\bar{J}} U_2$ has rank $n - k$.

As a consequence of these bounds, we have

$$c^2(p - r - n + k) \leq \text{tr}[(R_1 + R_2)^2] \leq r(O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right) + c)^2 + c^2(p - r - n + k),$$

or

$$\left| \text{tr}[(R_1 + R_2)^2] - c^2(p - r - n + k) \right| \leq r(O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right) + c)^2.$$

Similarly,

$$\left| \text{tr}[(R_1 + R_2)] - c(p - r - n + k) \right| \leq r(O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right) + c).$$

These, combined with the assumptions, yield

$$\text{tr}[(R_1 + R_2)^2] = (1 + o_P(1))c^2(p - r - n + k),$$

and

$$\text{tr}[(R_1 + R_2)] = c(p - r - n + k) + O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right).$$

Now we have the Lyapunov condition

$$\frac{\lambda_1[(R_1 + R_2)^2]}{\text{tr}[(R_1 + R_2)^2]} = \frac{(O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right) + c)^2}{(1 + o_P(1))c^2(p - r - n + k)} \xrightarrow{P} 0.$$

Apply Lyapunov central limit theorem conditioning on $H_{Z\tilde{J}}$, we have

$$(2 \operatorname{tr}[(R_1 + R_2)^2])^{-1/2} (G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) U \Lambda^{1/2} G_2 - \operatorname{tr}(R_1 + R_2) I_{k-1}) \xrightarrow{\mathcal{L}} W_{k-1}$$

where W_{k-1} is a $(k-1) \times (k-1)$ symmetric random matrix whose entries above the main diagonal are i.i.d. $N(0, 1)$ and the entries on the diagonal are i.i.d. $N(0, 2)$. By Slutsky's theorem, we have

$$(2c^2(p - r - n + k))^{-1/2} (G_2^T \Lambda^{1/2} U^T (I_p - H_{Z\tilde{J}}) U \Lambda^{1/2} G_2 - c(p - r - n + k) I_{k-1}) \xrightarrow{\mathcal{L}} W_{k-1}$$

As for the cross term of (10), we have

$$\begin{aligned} & \mathbb{E}[\|\mu_f^T(I_p - H_{Z\tilde{J}})U\Lambda^{1/2}G_2\|_F^2 | Z, \tilde{J}] \\ &= (k-1) \operatorname{tr}(\mu_f^T(I_p - H_{Z\tilde{J}})U\Lambda U^T(I_p - H_{Z\tilde{J}})\mu_f) \\ &\leq (k-1)\lambda_1((I_p - H_{Z\tilde{J}})U\Lambda U^T(I_p - H_{Z\tilde{J}}))\|\mu_f\|_F^2 \\ &= (k-1)O_P\left(\frac{\lambda_1 p}{\lambda_r n}\right)\|\mu_f\|_F^2 \\ &= (k-1)O_P\left(\frac{\lambda_1 \sqrt{p}}{\lambda_r n}\right)\sqrt{p}\|\mu_f\|_F^2 = o_P(p) \end{aligned}$$

The last equality holds when we assume $\frac{1}{\sqrt{p}}\|\mu_f\|_F^2 = O(1)$. Hence $\|\mu_f^T(I_p - H_{Z\tilde{J}})U\Lambda^{1/2}G_2\|_F^2 = o_P(p)$. This completes the proof of the theorem.
